## Chemical Calculations

Looking at the formation of ammonia

$$
\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NH}_{3}(\mathrm{~g})
$$

we can look at the moles of each to see the mole ratio of the reaction.

The mole ratio is a conversion factor derived from the coefficients of a balanced chemical equation.

In chemical calculations, mole ratios are used to convert between moles of reactants and moles of products, between moles of reactants, or between moles of products.

## Example

How many moles of ammonia are produced when 0.60 mol of nitrogen reacts with hydrogen?

There are 3 possible mole conversions we can look at

$$
\frac{1 \mathrm{~mol} \mathrm{~N}_{2}}{3 \mathrm{~mol} \mathrm{H}_{2}} \quad \frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{1 \mathrm{~mol} \mathrm{~N}_{2}} \quad \frac{3 \mathrm{~mol} \mathrm{H}_{2}}{2 \mathrm{~mol} \mathrm{NH}_{3}}
$$

We need to get from moles of nitrogen to moles of ammonia

$$
0.60 \mathrm{molN}_{2} \times \frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{1 \mathrm{molN}_{2}}=1.2 \mathrm{~mol} \mathrm{NH}_{3}
$$

> This is an example of a mole-mole calculation

## Example 2: Mass-Mass Calculations

Calculate the number of grams of $\mathrm{NH}_{3}$ produced by the reaction of 5.40 g of hydrogen with an excess of nitrogen. The balanced equation is

$$
\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NH}_{3}(\mathrm{~g})
$$

$$
5.40 \mathrm{~g} \mathrm{H}_{2} \times \frac{1 \mathrm{~mol} \mathrm{H}_{2}}{2.02 \mathrm{~g} \mathrm{H}_{2}} \times \frac{2 \mathrm{~mol} \mathrm{NH}_{3}}{3 \mathrm{~mol} \mathrm{H}_{2}} \times \frac{17.04 \mathrm{~g} \mathrm{NH}_{3}}{1 \mathrm{~mol} \mathrm{NH}_{3}}
$$

$$
\begin{aligned}
& 5.40 \mathrm{gHz} \times \frac{1 \mathrm{HH}_{2}}{2.02 \mathrm{H}_{2}} \times \frac{2 \mathrm{NH} \mathrm{H}_{3}}{3 \mathrm{H}} \times \frac{17.04 \mathrm{~g} \mathrm{NH}_{3}}{1 \mathrm{NH}_{3}}=30.36 \mathrm{~g} \mathrm{NH}_{3} \\
& =30.4 \mathrm{~g} \mathrm{NH} 3 \text { (3 sig dig) }
\end{aligned}
$$

## In a typical stoichiometric problem,

- The given quantity is first converted to moles.
- Then the mole ratio from the balanced equation is used to calculate the number of moles of the wanted substance.
- Finally, the moles are converted to any other unit of measurement related to the unit mole, as the problem requires.

Example 3 - Calculating Molecules of a Product
How many molecules of oxygen are produced when 29.2 grams of water is decomposed by electrolysis to this balanced equation?

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{I}) \stackrel{\text { electricity }}{ } 2 \mathrm{H}_{2}(g)+\mathrm{O}_{2}(g)
$$

## Example 4 - Volume-Volume Calculations

Nitrogen monoxide and oxygen gas combine to form the brown gas nitrogen dioxide, which contributes to smog. How many liters of nitrogen dioxide are produced when 34 L of oxygen reacts with an excess of nitrogen monoxide? Assume conditions of STP.

$$
2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

Example 5 - Finding the Volume of Gas

Assuming STP, how many milliliters of oxygen are needed to produce $20.4 \mathrm{~mL} \mathrm{SO}_{3}$ according to this balanced equation?

$$
2 \mathrm{SO}_{2}(g)+\mathrm{O}_{2}(g) \longrightarrow 2 \mathrm{SO}_{3}(g)
$$
